# Background: Systolic Array

# Challenges for Systolic Array

- **Sparse matrix multiplication is inefficient in systolic array**
- Disadvantages of systolic array
  - Not good at exploiting **irregular parallelism**
  - Relatively special purpose → need software, programmer support to be a general purpose model

Underutilization

# Previous work: Weight Pruning for Systolic Array

## Block-wise Pruning (DAC '19)

Pros:

- Less computation
- No input modification

Cons:

- Low compression ratio

	6		1		1		
2			2	1			
	3		2	4	3		3
6			2	4		2	2

			2	3			4

## Column Combining (ASPLOS '19)

Pros:

- Less computation
- Relative high accuracy (or low compression ratio)

Cons:

- Hard to find optimal group
- Rearrange input before computation
- MUX for each PE

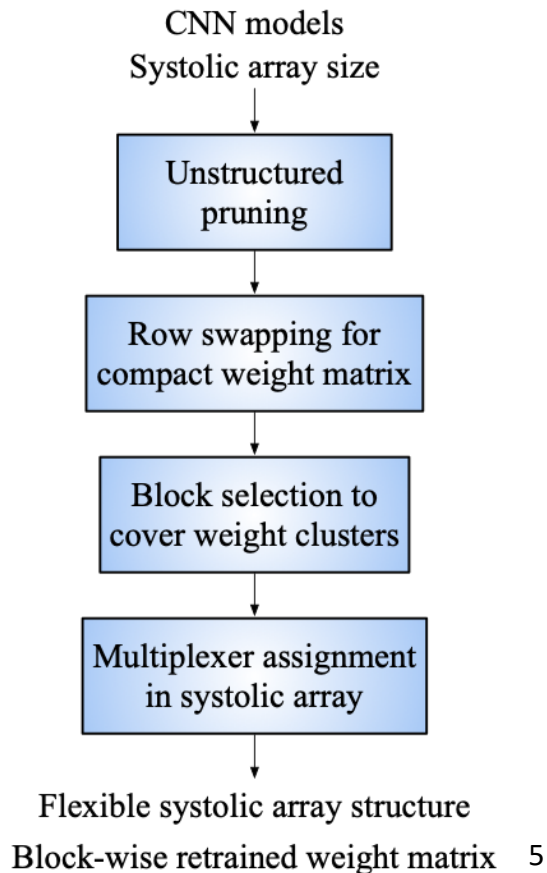

# Solution

---

To **fully** utilize the systolic array with **high compression ratio of CNN models**, we propose a **hardware-software codesign framework**.

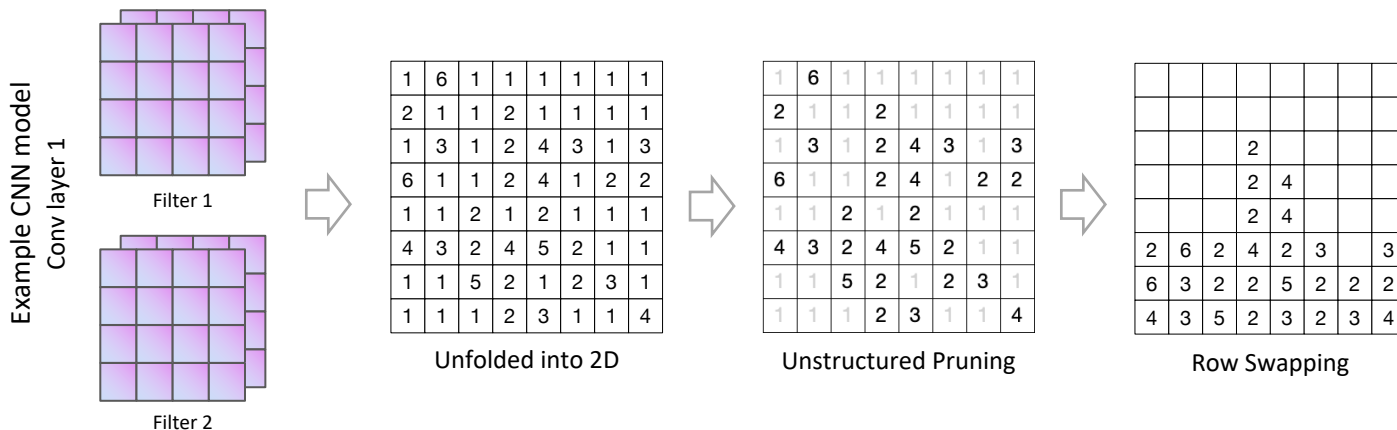

The framework outputs a **flexible** systolic array structure that sustains a balance between **latency** and **hardware cost** by:

- S Row swapping for compact storing of weight matrix
- S Block selection to cover the dense cluster of weights
- H Systolic array multiplexing
- H Genetic searching for flexible structure

# Unstructured Pruning and Row Swapping

- Unstructured pruning<sup>[1]</sup> is chosen to achieve a **high compression ratio**
- Row swapping is applied for compact weight matrix
  - Only **rows with non-zero weights** should be indexed when each column has weights
  - A small number of columns should be indexed only when some columns are empty

# Block Selection

- After **row swapping**, weights are reorganized into a **dense cluster**
- To find the optimal block set to cover the **weight cluster seamlessly**, we **enumerate** all the possible **block sets** according to the hardware constraint

# Microarchitecture of Systolic Array

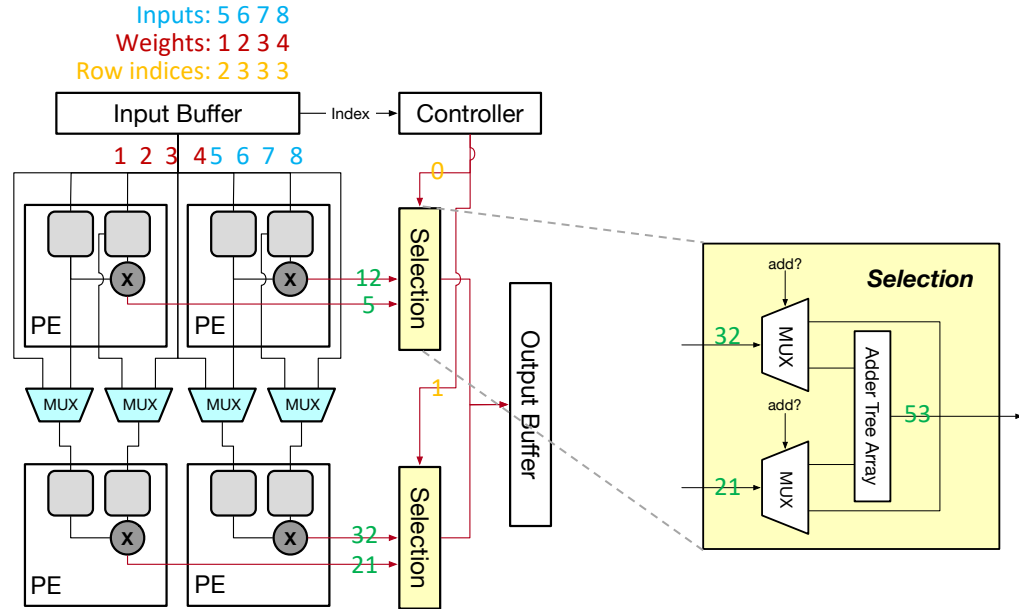

- To support the concurrent computations of various **blocks** with the corresponding inputs on systolic arrays, **multiplexers** are inserted into the arrays.
- To support the **row swapping**, a **controller** and **selection** modules are required to schedule the multiplication results.

# Computation of Modified Systolic Array

1. Decode row indices of weights by the **controller**
2. Load weights
3. Load inputs
4. Multiply weights and inputs
5. Transmit products to **selection** modules
6. **Controller** sends signal to **selection** modules
7. **Selection** modules handle received products
  - If weight are in the different row of the weight matrix, stores products respectively
  - If weights are in the same row of the weight matrix, add products and store the addition results

# Genetic Algorithm for Multiplexer Assignment

---

- The locations of multiplexers for **different CNN models** vary significantly
- A **genetic algorithm** is deployed to select where the **multiplexers** should be inserted considering both latency and hardware cost

---

## Algorithm 1: Genetic algorithm

---

START

- 1 Generate the initial population
  - 2 Compute fitness:  $E$
- REPEAT
- 3 Tournament selection
  - 4 Crossover
  - 5 Polynomial Mutation
  - 6 Compute fitness:  $E = C_l * L + C_a * A + C_w * W$

UNTIL stopping criteria are satisfied

---

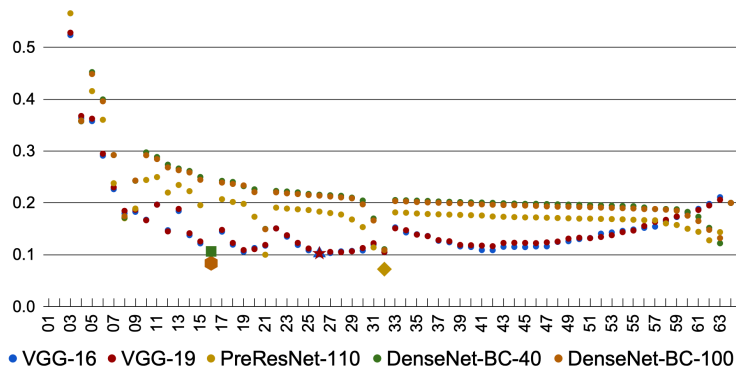

Mutation equation:  $x_i^{\{1,t+1\}} = x_i^{\{1,t\}} + \beta_i$

$$\beta_i = \begin{cases} (2u_i)^{\frac{1}{n_u+1}} - 1, & u_i < 0.5 \\ 1 - [2(1 - u_i)]^{\frac{1}{n_u+1}}, & u_i \geq 0.5 \end{cases}$$

# Experimental Results

Evaluation results for CNN models

Before genetic searching

After genetic searching

# Conclusion

---

- ❑ A **hardware-software codesign framework** is proposed to exploit systolic arrays for the computations of various CNNs efficiently
- ❑ By **row swapping**, **block selection**, **systolic array multiplexing** and **genetic searching for multiplexer assignment**, a flexible systolic array structure is developed with accordingly pruned CNN models
- ❑ The experimental results show that the **latency** can be **reduced** significantly with **low hardware cost** and **high inference accuracy**

# Q&A
